Future Work & Scalability Roadmap: MealMate

While the current version of MealMate (v1.0) successfully meets all initial functional and architectural requirements, the project has been designed with a modular foundation that allows for significant future expansion. Below is the proposed roadmap for scaling MealMate into a production-grade, multi-user consumer application.

🛠️ 1. Technical & Architectural Scaling

Full Cloud Persistence (Source of Truth Consolidation)

- **Current State**: Hybrid storage (SQLite for core data, LocalStorage for UI settings/budget).
- **Future Work**: Migrate all user-specific settings to the backend database. This would enable a seamless **multi-device experience**, where a user can plan a meal on their desktop and see the updated grocery list instantly on their mobile phone.

Advanced API Security & Observability

- **Current State**: Basic JWT authentication.
- **Future Work**:
  - Implement **Refresh Tokens** for safer, longer-lived sessions.
  - Add **Rate Limiting** to protect the backend from automated scraping.
  - Integrate **structured logging** (e.g., Winston/ELK stack) for production monitoring.

Performance Optimizations (PWA & Edge)

- **Current State**: Standard React SPA.
- **Future Work**: Convert the application into a **Progressive Web App (PWA)**. This would allow offline access to the grocery list and meal plan via service workers, which is critical for use inside grocery stores with poor signal.

✨ 2. Functional Feature Roadmap

AI-Powered Meal Recommendations

- **Concept**: Leverage machine learning to suggest recipes based on the user's historical preferences, dietary goals, and current pantry inventory.
- **Value**: Reduces "decision fatigue" for the user during the weekly planning phase.

Smart Recipe Scraping

- **Concept**: Allow users to paste a URL from any cooking blog and automatically "scrape" the ingredients and instructions into their personal MealMate library.
- **Value**: Drastically lowers the barrier to entry for users migrating from other platforms.

Collaborative Planning (Household Accounts)

- **Concept**: Enable multiple users (e.g., family members or roommates) to share a single "Home" account.
- **Value**: Allows real-time collaboration on grocery lists and meal rotations.

📈 3. Research & Sustainability

Nutrition & Macro Tracking

- **Concept**: Integrate a third-party nutrition API (like Edamam or Nutritionix) to display calories, protein, and micro-nutrients per serving.
- **Value**: Appeals to the health-conscious demographic and adds significant value beyond simple organization.

> *[!NOTE] **Reflection**: The current architecture uses a "Democractic Persistence" model (Local-first with API sync) which has proven highly resilient during development. The next logical step for the project would be a transition to a serverless edge architecture (e.g., Cloudflare D1/Workers) to support thousands of concurrent users globally.*
